Network Layer: The Control Plane
Software defined networking (SDN)

- Internet network layer: historically has been implemented via distributed, per-router approach
  - *monolithic* router contains switching hardware, runs proprietary implementation of Internet standard protocols (IP, RIP, IS-IS, OSPF, BGP) in proprietary router OS (e.g., Cisco IOS)
  - different “middleboxes” for different network layer functions: firewalls, load balancers, NAT boxes, ..

- ~2005: renewed interest in rethinking network control plane
Per-router control plane

Individual routing algorithm components *in each and every router* interact with each other in control plane to compute forwarding tables.
A distinct (typically remote) controller interacts with local control agents (CAs) in routers to compute forwarding tables.
Software defined networking (SDN)

Why a *logically centralized* control plane?

- easier network management: avoid router misconfigurations, greater flexibility of traffic flows
- table-based forwarding (recall OpenFlow API) allows “programming” routers
  - centralized “programming” easier: compute tables centrally and distribute
  - distributed “programming: more difficult: compute tables as result of distributed algorithm (protocol) implemented in each and every router
- open (non-proprietary) implementation of control plane
Vertically integrated
Closed, proprietary

Traffic engineering: difficult traditional routing

Q: what if network operator wants u-to-z traffic to flow along uvwz, x-to-z traffic to flow xwyz?

A: need to define link weights so traffic routing algorithm computes routes accordingly (or need a new routing algorithm)!

Link weights are only control “knobs”: wrong!
**Traffic engineering: difficult**

**Q:** what if network operator wants to split u-to-z traffic along uvwz and uxyz (load balancing)?

**A:** can’t do it (or need a new routing algorithm)
**Traffic engineering: difficult**

Q: what if w wants to route blue and red traffic differently?

A: can’t do it (with destination based forwarding, and LS, DV routing)
Software defined networking (SDN)

1. generalized "flow-based" forwarding (e.g., OpenFlow)

2. control, data plane separation

3. control plane functions external to data-plane switches

4. programmable control applications

Network Layer: Control Plane
**SDN perspective: data plane switches**

**Data plane switches**

- fast, simple, commodity switches implementing generalized data-plane forwarding (Section 4.4) in hardware
- switch flow table computed, installed by controller
- API for table-based switch control (e.g., OpenFlow)
  - defines what is controllable and what is not
- protocol for communicating with controller (e.g., OpenFlow)
**SDN perspective: SDN controller**

**SDN controller (network OS):**
- maintain network state information
- interacts with network control applications “above” via northbound API
- interacts with network switches “below” via southbound API
- implemented as distributed system for performance, scalability, fault-tolerance, robustness
**SDN perspective: control applications**

*network-control apps:*

- “brains” of control: implement control functions using lower-level services, API provided by SND controller
- *unbundled:* can be provided by 3rd party: distinct from routing vendor, or SDN controller

---

**Diagram:**

- **SDN Controller** (network operating system)
  - southbound API
  - northbound API

- **SDN-controlled switches**

- **network-control applications**
  - routing
  - access control
  - load balance

---

Network Layer: Control Plane 5-13
Components of SDN controller

- **Interface layer to network control apps**: abstractions API
- **Network-wide state management layer**: state of networks, links, switches, services: a *distributed database*
- **Communication layer**: communicate between SDN controller and controlled switches

---

**Network-wide distributed, robust state management**
- Link-state info
- Host info
- Switch info

**Communication to/from controlled devices**
- OpenFlow
- SNMP

**Interface, abstractions for network control apps**
- Network graph
- RESTful API
- Intent
- Statistics
- Flow tables

---

SDN controller
OpenFlow protocol

- operates between controller, switch
- TCP used to exchange messages
  - optional encryption
- three classes of OpenFlow messages:
  - controller-to-switch
  - asynchronous (switch to controller)
  - symmetric (misc)
OpenFlow: controller-to-switch messages

Key controller-to-switch messages

- **features**: controller queries switch features, switch replies
- **configure**: controller queries/sets switch configuration parameters
- **modify-state**: add, delete, modify flow entries in the OpenFlow tables
- **packet-out**: controller can send this packet out of specific switch port
OpenFlow: switch-to-controller messages

Key switch-to-controller messages

- **packet-in**: transfer packet (and its control) to controller. See packet-out message from controller
- **flow-removed**: flow table entry deleted at switch
- **port status**: inform controller of a change on a port.

Fortunately, network operators don’t “program” switches by creating/sending OpenFlow messages directly. Instead use higher-level abstraction at controller.
SDN: control/data plane interaction example

1. S1, experiencing link failure using OpenFlow port status message to notify controller

2. SDN controller receives OpenFlow message, updates link status info

3. Dijkstra's routing algorithm application has previously registered to be called when ever link status changes. It is called.

4. Dijkstra's routing algorithm access network graph info, link state info in controller, computes new routes

- control apps separate from controller
- intent framework: high-level specification of service: what rather than how
- considerable emphasis on distributed core: service reliability, replication, performance scaling
SDN: selected challenges

- hardening the control plane: dependable, reliable, performance-scalable, secure distributed system
  - robustness to failures: leverage strong theory of reliable distributed system for control plane
  - dependability, security: “baked in” from day one?
- networks, protocols meeting mission-specific requirements
  - e.g., real-time, ultra-reliable, ultra-secure
- Internet-scaling
